**Abstract**—The purpose of this study was to determine if there were differences in the prevalence of musculoskeletal disorders between two groups of nurses working in different departments. The sample consisted of 100 nurses from two departments of a tertiary care hospital. Data were collected by means of a self-administered questionnaire. Results showed that the prevalence of musculoskeletal disorders was higher among nurses who worked in the intensive care unit than among those who worked in the medical-surgical department. It was concluded that the prevalence of musculoskeletal disorders is related to the type of work performed.
